A 65-year-old woman presented with 7 days of productive cough and the new onset sharp central chest pain. She has a known history of chronic sinusitis and COPD after being a 50 pack-year smoker. On examination, her blood pressure was 116/70 with a heart rate of 86 (sinus rhythm) and oxygen saturations were 93% on 4L/min by nasal cannula. She had bilateral expiratory wheezes with reduced air entry on the left side.

An AP chest x-ray revealed dextrocardia with a left sided tension pneumothorax (Figure 1A). Our patient was stabilized with an urgent chest tube insertion and taken for a CT chest and abdomen. CT chest indicated diffuse bronchiectasis (Figure 1B, arrow) with a CT of the abdomen showing reversal of major abdominal organs (Figure 1C).

First described in 1933, the triad of chronic sinusitis, bronchiectasis, and situs inversus is classic for Kartagener syndrome (1). Otherwise known as primary ciliary dyskinesia, it is an autosomal recessive disorder affecting the dynein motor protein on microtubules. Ciliary dysfunction from an embryonic stage is the underlying cause for 50% of patients with situs inversus (2). Ongoing difficulties clearing mucous and secretions from abnormal ciliary movements accelerates.
the development of rhinosinusitis and bronchiectasis (3). Fertility is also a common concern with most males being infertile and females having a lower likelihood of successful pregnancy (4).

Confirmatory testing requires electron microscopy to determine ultrastructure and high-speed video microscopy to determine abnormal movement of cilia (4). Long-term management involves control of respiratory complications with regular spirometry and pulmonary follow up.
